A Project Report on

AI Generated Image Detection

Submitted in partial fulfilment for award of
Bachelor of Technology
Degree

in

CSE (Artificial Intelligence and Machine Learning)

By

S. Susmitha (Y22ACM478)

V. Naga Pujitha (Y22ACM485)

P. Gopi Chand (Y22ACM463)

Y.L. Surendra (L23ACM502)

Under the guidance of
V. ROSHAN KUMAR, M. Tech
Assistant Professor

Department of CSE (Artificial Intelligence & Machine Learning)

Bapatla Engineering College
(Autonomous)
(Affiliated to Acharya Nagarjuna University)
BAPATLA – 522 102, Andhra Pradesh, INDIA

2025-2026

Department of
CSE (Artificial Intelligence and Machine Learning)

CERTIFICATE

This is to certify that the project report entitled **AI Generated Image Detection** being submitted by SYPU SUSMITHA (Y22ACM478), VARI NAGA PUJITHA (Y22ACM485), PASAM GOPI CHAND (Y22ACM463), and YARRAREDDI LAKSHMI SURENDRA (L23ACM502) in partial fulfilment for the award of the Degree of Bachelor of Technology in CSE(Artificial Intelligence and Machine Learning) to the Acharya Nagarjuna University is a record of bonafide work carried out by them under our guidance and supervision.

Date:

Signature of the Guide	**Signature of the HOD**
V. Roshan Kumar	**Dr. K. Manideep**
Assistant Professor	**Assoc. Prof. & Head**

DECLARATION

We declare that this project work is composed by ourselves, that the work contained herein is our own except where explicitly stated otherwise in the text, and that this work has not been submitted for any other degree or professional qualification except as specified.

SYPU SUSMITHA (Y22ACM478)

VARI NAGA PUJITHA (Y22ACM485)

PASAM GOPI CHAND (Y22ACM463)

YARRAREDDI LAKSHMI SURENDRA (L23ACM502)

ACKNOWLEDGEMENT

We sincerely thank the following distinguished personalities who have given their advice and support for successful completion of the work.

We are deeply indebted to our most respected guide **V. Roshan Kumar,** Assistant Professor, Department of CSE(AIML), for her valuable and inspiring guidance, comments, suggestions and encouragement.

We extend our sincere thanks to **Dr. K. Manideep,** Assoc. Prof. & Head, Department of CSE(AIML) for extending his cooperation and providing the required resources.

We would like to thank our beloved Principal **Dr. B. Srinivasa Rao** for providing the online resources and other facilities to carry out this work.

We would like to sincerely thank our project coordinator **Ms. G. V. Leela Kumari**, Assistant Prof., Dept. of CSE(AIML), for her helpful suggestions in presenting this document.

We extend our sincere thanks to all other teaching faculty and non-teaching staff of the department, who helped directly or indirectly for their cooperation and encouragement.

SYPU SUSMITHA (Y22ACM478)
VARI NAGA PUJITHA (Y22ACM485)
PASAM GOPI CHAND (Y22ACM463)
YARRAREDDI LAKSHMI SURENDRA (L23ACM502)

ABSTRACT

This project presents an advanced intelligent system for detecting whether an image is real or AI-generated by integrating deep learning techniques with detailed image feature analysis. The core of the system is based on a Convolutional Neural Network (CNN) model that performs classification by learning complex visual patterns from image data, supported by handcrafted features such as noise score, edge density, brightness, contrast, and colour variance, which help in identifying subtle inconsistencies between natural and synthetic images. These combined features significantly improve the accuracy and robustness of detection. A major highlight of the system is the incorporation of explainable AI, which not only provides classification results but also generates clear, human-readable explanations for each prediction, thereby enhancing transparency, interpretability, and user trust. Furthermore, the system includes an automated report generation module that produces comprehensive PDF reports containing the prediction outcome, confidence score, feature analysis, and explanatory insights. The implementation leverages powerful technologies such as TensorFlow for model building and inference, OpenCV for image preprocessing and feature extraction, and Gradio for developing an interactive and user-friendly interface that supports both single and batch image uploads. The system is designed to be efficient, scalable, and easy to use, making it highly suitable for real-world applications such as digital forensics, social media content verification, cybersecurity, and detection of AI-generated media, ultimately contributing to more reliable, secure, and trustworthy image analysis solutions.

Keywords: Image Detection, Convolutional Neural Networks (CNNs), Local Features, Shared Weights, Pooling Mechanisms, ShortCut3-ResNet, Residual Network (ResNet), Feature Extraction, Explainable AI, PDF Report Generation.

CHAPTER 1
INTRODUCTION

1.1 Background of the Study

In recent years, Artificial Intelligence (AI) has experienced rapid growth, particularly in the field of computer vision and image processing. Advanced deep learning techniques such as Generative Adversarial Networks (GANs) and Variational Autoencoders (VAEs) have made it possible to generate highly realistic synthetic images. These AI-generated images are often visually indistinguishable from real-world photographs, making them increasingly difficult to identify using traditional methods.

The widespread availability of such technologies has brought significant benefits across multiple domains including entertainment, digital media, gaming, healthcare, and design. For instance, AI-generated images are used in creating realistic animations, enhancing image quality, and generating synthetic data for training machine learning models. However, alongside these benefits, there are serious concerns regarding the misuse of AI-generated content. Fake images can be used for spreading misinformation, creating deepfakes, manipulating public opinion, and compromising digital trust.

As a result, there is a growing demand for intelligent systems that can accurately differentiate between real and AI-generated images. This project focuses on addressing this challenge by developing an advanced image authenticity detection system. The proposed system integrates Convolutional Neural Networks (CNNs) with traditional image processing techniques to analyze both deep features and handcrafted visual characteristics.

Additionally, the project emphasizes the importance of explainable AI. Unlike conventional black-box models, the proposed system provides human-readable explanations for its predictions, enabling users to understand the reasoning behind classification decisions. This improves transparency, reliability, and user confidence in the system.

1.2 Problem Statement

With the increasing sophistication of AI-based image generation techniques, distinguishing between real and synthetic images has become a complex and critical problem. Traditional image detection systems primarily rely on large volumes of annotated training data to learn patterns and features. However, acquiring such datasets is both time-consuming and resource-intensive.

One of the major challenges is the scarcity of high-quality annotated datasets. Manual labelling of images requires significant effort and expertise, which limits the size and diversity of training data. As a result, models trained on limited datasets often fail to generalize well when exposed to new or unseen data.

Another significant issue is that AI-generated images continue to evolve rapidly. Modern generation techniques produce images with fewer artifacts and more realistic textures, making it increasingly difficult for conventional detection methods to identify subtle differences. CNN-based models may struggle to detect these variations if they are not adequately trained with diverse data.

Therefore, the problem addressed in this project is to design a robust, accurate, and explainable system capable of detecting AI-generated images while overcoming limitations such as data scarcity, poor generalization, and lack of transparency.

1.3 Objectives of the Project

The primary aim of this project is to develop an intelligent system for detecting AI-generated images using advanced machine learning techniques. The key objectives are outlined as follows:

- To design and implement a Convolutional Neural Network (CNN)-based model for image classification
- To accurately distinguish between real and AI-generated images using deep learning techniques
- To enhance detection performance by incorporating handcrafted feature analysis such as noise score, edge density, brightness, contrast, and colour variance
- To improve model robustness and generalization by utilizing augmented datasets
- To integrate explainable AI techniques that provide clear and human-readable explanations for predictions
- To develop an automated report generation system that produces detailed analysis results in PDF format
- To enable batch processing for analysing multiple images efficiently
- To ensure the system is user-friendly and accessible through an interactive interface
- The primary aim of this project is to develop an intelligent and efficient system capable of detecting whether an image is real or AI-generated by leveraging advanced machine learning and deep learning techniques. With the rapid growth of AI-generated content,

there is an increasing need for reliable systems that can accurately identify synthetic images and ensure authenticity in digital media. This project focuses on building a robust and scalable solution that not only performs classification but also provides meaningful insights into the decision-making process.

- One of the key objectives of this project is to design and implement a Convolutional Neural Network (CNN)-based model for image classification. CNNs are highly effective in processing visual data and are capable of learning complex patterns and features from images. By utilizing CNN architecture, the system aims to achieve high accuracy in distinguishing between real and AI-generated images.
- Another important objective is to accurately classify images using deep learning techniques. The system is trained on a dataset containing both real and synthetic images, enabling it to learn distinguishing characteristics and improve prediction performance. In order to further enhance detection accuracy, the project incorporates handcrafted feature analysis. Features such as noise score, edge density, brightness, contrast, and colour variance are extracted from images to capture subtle differences that may not be easily detected by deep learning alone.
- Improving the robustness and generalization capability of the model is also a major objective. This is achieved by utilizing augmented datasets, which include variations in lighting conditions, orientations, and image quality. Data augmentation helps the model perform well on unseen data and reduces the risk of overfitting.
- The project also aims to integrate explainable AI techniques into the system. Unlike traditional black-box models, this system provides clear and human-readable explanations for its predictions. This enhances transparency and helps users understand the reasoning behind the classification results, thereby increasing trust in the system.
- Another objective is to develop an automated report generation module that produces detailed PDF reports. These reports include prediction results, confidence scores, feature analysis, and explanations, making the system more practical and useful for real-world applications. Additionally, the system supports batch processing, allowing multiple images to be analysed simultaneously, which improves efficiency and scalability.
- Finally, the project aims to ensure that the system is user-friendly and accessible through an interactive interface. The interface is designed to be simple and intuitive, enabling users with minimal technical knowledge to use the system effectively. Overall,

these objectives collectively contribute to building a reliable, accurate, and user-centric image detection system.

1.4 Scope of the Project

The scope of this project focuses on the development and implementation of an AI-based image authenticity detection system. The system is designed to analyze input images and classify them as either real or AI-generated based on learned patterns and extracted features.

The project includes the following key aspects:

- Image input and preprocessing techniques such as resizing and normalization
- Feature extraction using image processing methods to capture important visual characteristics
- CNN-based classification for detecting image authenticity
- Implementation of explainable AI for generating meaningful insights into model decisions
- Automated PDF report generation containing predictions, confidence scores, and feature analysis
- Batch processing capability to handle multiple images simultaneously
- Digital forensics for detecting manipulated or fake images
- Social media platforms for content verification
- Cybersecurity for identifying fraudulent visual data
- Media and journalism for ensuring authenticity of visual content

However, the project has certain limitations that need to be considered. The system's performance may be affected when dealing with highly advanced AI-generated images created using newer techniques that were not included in the training dataset. As AI image generation models continue to evolve rapidly, they produce increasingly realistic outputs with fewer detectable artifacts. This makes it challenging for the current model to generalize effectively to such unseen data, potentially reducing its accuracy in certain cases.

Additionally, the use of lower-resolution images for training may limit the system's ability to detect fine-grained details present in high-resolution images. Subtle visual inconsistencies, textures, and artifacts that distinguish real images from synthetic ones may not be fully captured at lower resolutions. Despite these limitations, the system provides a strong foundation for future improvements and real-world deployment, as it can be further enhanced through better datasets, advanced models, and improved feature extraction techniques.

1.5 Organisation of the Report

This report is structured in a systematic and well-organized manner to present the complete details of the project in a clear and logical sequence. Each chapter focuses on a specific aspect of the system, ensuring that the reader can easily understand the objectives, design, implementation, and outcomes of the project. The structured approach not only improves readability but also provides a comprehensive understanding of the work carried out.

Chapter1: Introduction

This chapter provides a detailed overview of the project. It introduces the background of the study, highlighting the importance of detecting AI-generated images in today's digital world. It also defines the problem statement, outlines the objectives of the project, and explains the scope and significance of the proposed system. This chapter sets the foundation for understanding the motivation behind the project and its overall goals.

Chapter2: Literature Survey

This chapter presents a review of existing research work related to image detection and AI-generated content. It discusses various methodologies, algorithms, and technologies used by previous researchers in this domain. The chapter also analyzes the strengths and limitations of existing systems, providing insights into the gaps that the proposed project aims to address. This helps in establishing the relevance and necessity of the current work.

Chapter 3: System Analysis & Design

This chapter explains the design and architecture of the proposed system in detail. It includes system architecture diagrams, UML diagrams such as use case, class, sequence, and activity diagrams, and a description of system components. It also covers the implementation details, development environment, and working of the Convolutional Neural Network (CNN) model. This chapter provides a technical understanding of how the system is designed and developed.

Chapter 4: Results

This chapter presents the output of the system along with performance evaluation. It includes screenshots of the system interface, classification results, and generated reports. The chapter also discusses important performance metrics such as accuracy, precision, recall, and F1 score.

Detailed analysis of the results is provided to demonstrate the effectiveness and reliability of the system.

Chapter 5: Conclusion

This chapter summarizes the overall achievements and outcomes of the project. It highlights the key contributions, findings, and success of the system in detecting AI-generated images. The chapter also provides insights into the effectiveness of the proposed approach and its potential applications in real-world scenarios.

CHAPTER 2
LITERATURE REVIEW

2.1 Overview of Existing Work

In recent years, Convolutional Neural Networks (CNNs) have become the dominant approach in image detection and classification tasks. The breakthrough work of AlexNet demonstrated the power of deep learning in image recognition, which led to the development of more advanced architectures such as VGG, ResNet, and EfficientNet. These models significantly improved accuracy and efficiency in handling complex visual data.

Several researchers have contributed to the advancement of image detection techniques. Tian (2020) proposed a CNN model combined with Recurrent Neural Networks (RNNs) to improve learning capability and recognition accuracy. Karandikar et al. (2020) developed a CNN-based model for detecting inconsistencies in video frames, particularly useful in identifying manipulated content. Yadav and Balabantaray (2022) focused on EfficientNet-based architectures, showing improved performance in image classification tasks.

Recent studies have also focused on detecting AI-generated images. Jiang et al. (2023) introduced methods involving histogram and residual image analysis to enhance robustness against synthetic images. Xi et al. (2023) proposed a framework using CNN and transfer learning with Class Activation Maps (CAM) to distinguish real and generated images. Baraheem and Nguyen (2023) analysed the capability of AI systems to detect AI-generated content and highlighted the challenges involved.

Additionally, the use of Generative Adversarial Networks (GANs) and Variational Autoencoders (VAEs) has been explored to generate synthetic images for data augmentation. These techniques help in increasing dataset diversity and improving the performance of CNN models.

Despite these advancements, several challenges still remain in the field of image detection and AI-generated content identification. Many of the existing approaches struggle to maintain high accuracy when dealing with increasingly sophisticated synthetic images produced by modern generative models. Moreover, issues such as dataset bias, lack of interpretability, and high computational requirements continue to affect the practical deployment of these models.

2.2 Comparison of Previous Approaches

The existing approaches for image detection and AI-generated image identification differ significantly in terms of methodology, performance, and inherent limitations. Over the years, various deep learning techniques have been proposed to improve detection accuracy; however, each approach comes with its own set of challenges that impact overall system effectiveness.

Traditional Convolutional Neural Network (CNN)-based systems have been widely used due to their ability to automatically learn hierarchical features directly from image data. These models have achieved high accuracy in image classification and detection tasks. However, their performance heavily depends on the availability of large-scale annotated datasets. The process of collecting and labeling such datasets is time-consuming, expensive, and often impractical, especially in specialized domains. Additionally, limited dataset diversity can lead to overfitting, where the model performs well on training data but fails to generalize effectively to new or unseen images.

To enhance feature learning capabilities, some approaches combine CNNs with Recurrent Neural Networks (RNNs). These hybrid models aim to capture both spatial and sequential information, resulting in improved accuracy. However, this improvement comes at the cost of increased computational complexity and higher resource requirements, making them less suitable for real-time or large-scale applications. Similarly, advanced architectures such as EfficientNet focus on optimizing performance and efficiency through better scaling techniques. While these models provide improved accuracy with fewer parameters, they still rely heavily on the quality and size of the training dataset.

In the context of AI-generated image detection, several methods utilize feature-based analysis techniques such as histogram analysis, residual image analysis, and texture-based features. These methods help identify inconsistencies and artifacts present in synthetic images. While effective to some extent, they often struggle when dealing with highly realistic images generated by modern AI techniques, which produce fewer visible artifacts and more natural-looking textures.

Transfer learning has also been widely adopted to improve model performance by leveraging pre-trained models. This approach reduces training time and data requirements while enhancing detection accuracy. However, transfer learning models may not always adapt well to domain-specific variations, limiting their effectiveness in certain scenarios.

Another important advancement is the use of Generative Adversarial Networks (GANs) to generate synthetic images for data augmentation. Integrating GAN-generated images into

training datasets helps improve model robustness and generalization by introducing diverse training samples. Despite these advantages, this approach introduces new challenges, including the risk of incorporating biased or low-quality synthetic data, which can negatively affect model performance.

Overall, although existing approaches have made significant progress in image detection and AI-generated image identification, they still face several limitations. These include dependency on large datasets, difficulty in generalization, high computational cost, and ethical concerns such as bias and lack of transparency. These challenges highlight the need for a more robust, efficient, and explainable system, which is the primary focus of the proposed project.

CHAPTER 3
SYSTEM DESIGN

3.1 Existing System

Traditional CNN-based image recognition systems rely heavily on annotated training datasets to learn object representations directly from raw pixel data. These systems have achieved significant success in various domains, including object recognition, scene understanding, and semantic segmentation. However, several limitations and challenges exist within the existing paradigm.

3.1.1 Disadvantages of Existing System

- **Data Scarcity and Annotation Costs:** Manual annotation of large-scale datasets is labour-intensive, time-consuming, and costly. Annotated datasets may be limited in size and scope, especially for niche or specialized domains.
- **Limited Diversity in Training Data:** Traditional datasets may not adequately capture the full diversity of real-world scenarios, leading to models that are biased or lack generalization capability.
- **Difficulty in Generalization to Novel Environments:** CNN-based image recognition systems often face challenges in generalizing to novel or unseen environments exhibiting a wide range of contextual factors, occlusions, and ambiguities.
- **Ethical and Fairness Concerns:** Traditional systems may inadvertently perpetuate biases present in the training data, leading to unfair or discriminatory outcomes in sensitive domains such as healthcare, criminal justice, and surveillance.
- **Computational and Resource Constraints:** Training CNN models requires significant computational resources, including high-performance GPUs and large memory capacities.
- **Lack of Explainability:** Traditional CNN-based systems often act as black-box models, providing predictions without clear explanations. This lack of interpretability makes it difficult for users to understand the reasoning behind decisions, reducing trust and reliability in critical applications.
- **Sensitivity to Noise and Image Variations:** Existing systems can be sensitive to noise, lighting conditions, and image quality variations. Small changes in input images, such

as blur, compression, or illumination differences, may significantly affect model performance and lead to incorrect predictions.

3.1.2 Summary

Existing Convolutional Neural Network (CNN)-based image recognition systems have demonstrated significant success in various computer vision tasks; however, they also exhibit several limitations that affect their overall performance, applicability, and ethical robustness. One of the major challenges faced by these systems is data scarcity and the high cost of annotation. Creating large-scale annotated datasets requires extensive manual effort, time, and expertise, making it difficult to obtain sufficient high-quality data, especially for specialized or niche domains. This limitation directly impacts the model's ability to learn effectively and generalize across different scenarios.

Another important issue is the limited diversity in training data**.** Traditional datasets may not capture the full range of real-world variations such as changes in lighting, background, object orientation, and environmental conditions. As a result, models trained on such datasets may become biased toward specific patterns and fail to perform accurately when exposed to unfamiliar or diverse inputs. This leads to reduced generalization capability, which is a critical requirement for real-world applications.

CNN-based systems also face challenges in generalizing to novel or unseen environments. Real-world data is often complex and dynamic, involving occlusions, distortions, and varying contextual factors. Models that are not trained on sufficiently diverse data may struggle to adapt to these variations, resulting in decreased accuracy and reliability. Additionally, ethical and fairness concerns arise due to biases present in training datasets. These biases can lead to unfair or discriminatory outcomes, particularly in sensitive domains such as healthcare, surveillance, and decision-making systems, raising serious ethical implications.

Furthermore, computational and resource constraints pose another limitation. Training deep learning models, especially CNNs, requires significant computational power, including high-performance GPUs and large memory capacities. This makes it difficult for smaller organizations or individuals with limited resources to develop and deploy such systems effectively. In addition, many traditional systems lack explainability**,** making it difficult for users to understand how decisions are made, which reduces transparency and trust.

To address these challenges, several strategies can be adopted. One effective approach is the use of AI-generated images to augment training datasets, thereby increasing data diversity and reducing dependence on manually annotated data. Techniques such as data augmentation and synthetic data generation can help improve model robustness and generalization. Additionally, domain adaptation and transfer learning techniques can be used to enhance the model's ability to perform well across different environments and datasets.

Promoting fairness and ethical AI practices is also essential to ensure that models do not produce biased or discriminatory outcomes. This can be achieved through careful dataset selection, bias detection methods, and fairness-aware learning techniques. Moreover, incorporating explainable AI methods can improve transparency by providing clear insights into the model's decision-making process.

In conclusion, while existing CNN-based systems have achieved considerable success, addressing these limitations is crucial for developing more reliable, efficient, and ethically responsible image recognition systems. By adopting advanced techniques and improving data quality, future systems can overcome these challenges and deliver better performance in real-world applications.

3.2 Proposed System

The proposed system aims to address the limitations of existing CNN-based image detection systems by integrating AI-generated images into the training pipeline. By leveraging advanced AI techniques such as Generative Adversarial Networks (GANs) and Variational Autoencoders (VAEs), synthetic images are generated to augment the training dataset, thereby enhancing model performance, robustness, and ethical soundness.

- **Augmentation of Training Dataset:** The system augments the traditional annotated training dataset with AI-generated images synthesized using GANs. These synthetic images simulate diverse environmental conditions, lighting variations, object orientations, and occlusions.
- **Enhancement of Model Robustness:** By exposing the CNN model to a more comprehensive set of training examples, the proposed system seeks to enhance the model's robustness to variations not encountered during training.

- **Mitigation of Bias and Ethical Concerns:** A key focus of the proposed system is to mitigate biases present in the training data and promote ethical AI development practices through adversarial training and fairness-aware learning.
- **Improving Generalization to Novel Environments:** Synthetic images generated to simulate various environmental conditions and object variations help the model learn robust representations that generalize effectively across different contexts.
- **Validation and Evaluation:** The effectiveness of the proposed system is validated through comprehensive experimentation using quantitative metrics such as accuracy, precision, recall, and F1 score.

3.2.1 Advantages of Proposed System

- **High Accuracy:** CNN-based image detection systems have demonstrated state-of-the-art performance in object recognition, scene understanding, and semantic segmentation tasks.
- **Efficiency:** Despite their complexity, CNN architectures are designed to be computationally efficient, allowing for fast inference times even on resource-constrained devices.
- **End-to-End Learning:** CNNs are capable of learning hierarchical representations directly from raw pixel data, eliminating the need for handcrafted features or preprocessing steps.
- **Adaptability:** CNN-based image detection systems are highly adaptable and can be trained on diverse datasets representing different domains, environments, and object classes.
- **Scalability:** CNN architectures can be scaled up or down to accommodate different levels of complexity and computational resources.
- **Interpretability:** Techniques such as activation visualization, gradient-based attribution methods, and saliency maps provide insights into which image regions contribute most to the model's predictions.

3.3 Feasibility Study

The feasibility study examines the project's practicability across three dimensions: Technical, Economical, and Social Feasibility.

3.3.1 Technical Feasibility

Technical feasibility involves evaluating the availability of necessary technology, equipment, and expertise to develop and deploy the project. The required technologies for image processing, natural language processing, and machine learning — such as TensorFlow, Keras, and OpenCV — exist and are widely used in the industry. Standard computer systems with GPUs can handle the computational requirements. The system is designed to be modular and scalable, allowing for easy upgrades and enhancements. New features and improvements can be integrated without requiring major changes to the existing architecture.

3.3.2 Economical Feasibility

Economic feasibility involves evaluating the costs associated with the project against the benefits or returns expected. The development costs are minimized by leveraging existing open-source resources and technologies, thereby reducing expenditure. Operational costs are kept low, with no need for additional hardware beyond what is already available. The potential benefits of the system — such as improved productivity, enhanced content verification, and digital security — outweigh the costs, ensuring a positive return on investment.

3.3.3 Social Feasibility

Social feasibility refers to the assessment of whether a proposed project is acceptable to the society or community in which it will be implemented. The AI image detection system is anticipated to garner substantial support from both management and users due to its alignment with current needs for digital content verification. The system's design emphasizes ease of use and accessibility, which should facilitate user acceptance and adoption. While there may be initial challenges in terms of user acceptance, the system is well-positioned to become an integral part of digital content verification workflows.

3.4 REQUIREMENTS

3.4.1 Hardware Requirements

- System: Intel Core i5 CPU
- Hard Disk: 500 GB
- GPU: NVIDIA GPU
- RAM: 16 GB

3.4.2 Software Requirements

- Operating System: Windows 11
- Programming Language: Python
- Tool: Anaconda
- Libraries: Gradio, TensorFlow, OpenCV, FPDF, NumPy, Matplotlib

CHAPTER 4
SYSTEM DESIGN

4.1 Architecture Design

The system architecture of the AI Image Detection System is designed to process input images through multiple stages, ensuring accurate classification and detailed analysis. The architecture follows a modular approach where each component performs a specific function in the workflow.

The process begins with the Input Module, where users upload one or multiple images. These images are then passed to the Preprocessing Module, which performs operations such as resizing and normalization to prepare the data for further processing.

Next, the Feature Extraction Module analyses important visual characteristics such as noise score, edge density, brightness, contrast, and colour variance. These features help in identifying subtle differences between real and AI-generated images.

The processed data is then fed into the CNN Prediction Module, which classifies the image as either REAL or AI-GENERATED and assigns a confidence score. Following this, the Decision Explanation Module generates human-readable explanations based on the extracted features.

Finally, the Report Generation Module creates a detailed PDF report containing prediction results, feature analysis, and explanations. The system also supports Batch Processing, allowing multiple images to be analysed simultaneously.

The system architecture encompasses the following modules working in sequence: Input Module (accepts image files), Pre-Processing Module (resizes and normalizes images), Feature Extraction Module (extracts noise, edges, brightness, contrast, colour variance), CNN Prediction Module (classifies as REAL or AI-GENERATED), Decision Explanation Module (generates human-readable explanations), Report Generation Module (creates PDF reports), Batch Processing Module (handles multiple images), and Output Module (displays results and allows download).

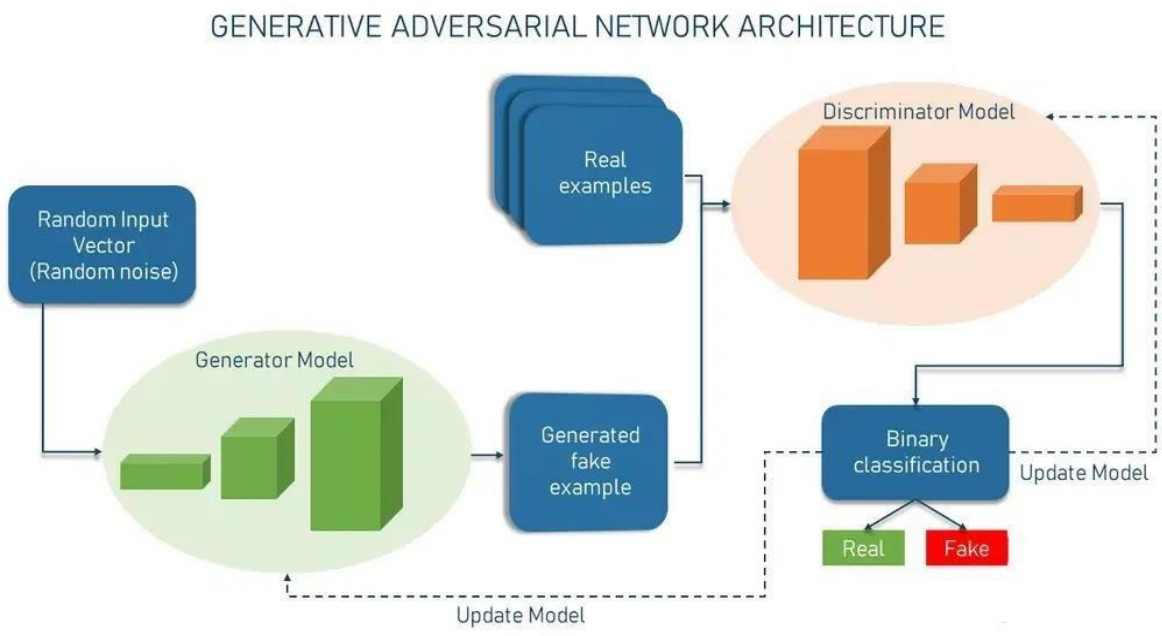

Fig. 4.1 System Architecture

4.2 UML Diagrams

UML (Unified Modelling Language) diagrams are used to represent the system structure and behaviour from different perspectives.

4.2.1 Use Case Diagram

The Use Case Diagram provides a high-level overview of system functionality from the user's perspective. The primary actor is the user, who interacts with the system to upload images and view results.

The main use cases include:

- Upload Image
- Preprocessing
- CNN Processing
- Feature Extraction
- View Results and Reports

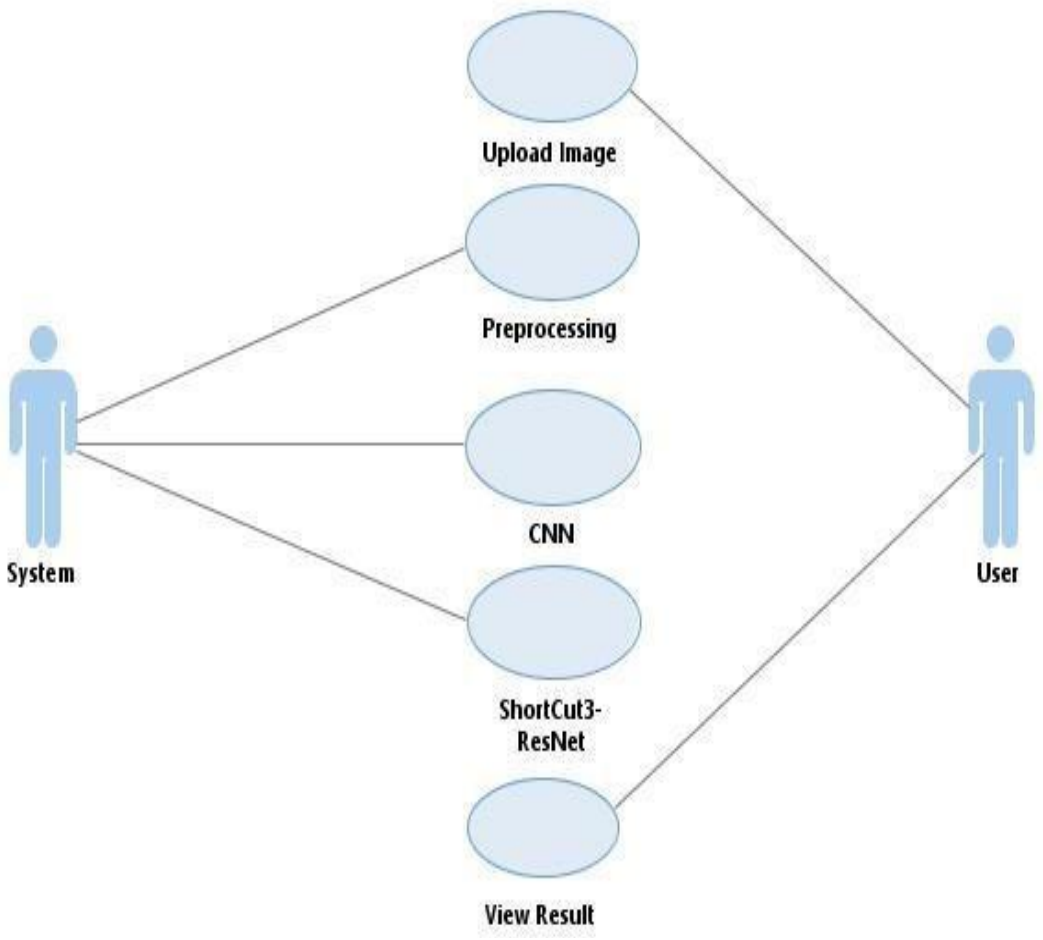

Fig 4.2 Use Case Diagram

4.2.2 Class Diagram

The Class Diagram represents the static structure of the system by defining classes and their relationships.

Key classes include:

User – interacts with the system

Image Preprocessing – handles resizing and normalization

CNN Model – performs image classification

Feature Extractor – extracts image features

Result Display – presents results and reports

These classes work together to implement the complete system functionality.

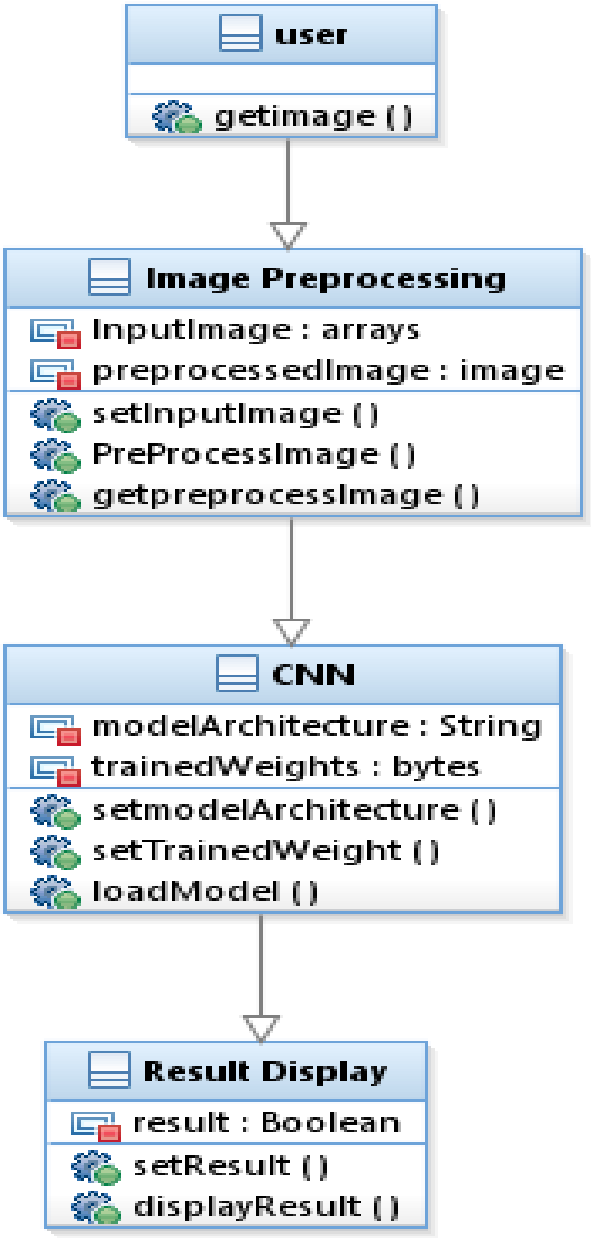

Fig. 4.3 Class Diagram

4.2.3 Sequence Diagram

The Sequence Diagram illustrates how objects interact in the image detection scenario. The flow of interactions is as follows: The user selects and uploads an image through the UI. The UI displays the selected image and sends the image data to the preprocessing module. The preprocessing module processes the image (resizing, normalization) and sends the pre-processed image to the CNN. The CNN processes the image and generates a result that is sent back to the UI, which displays the result to the user.

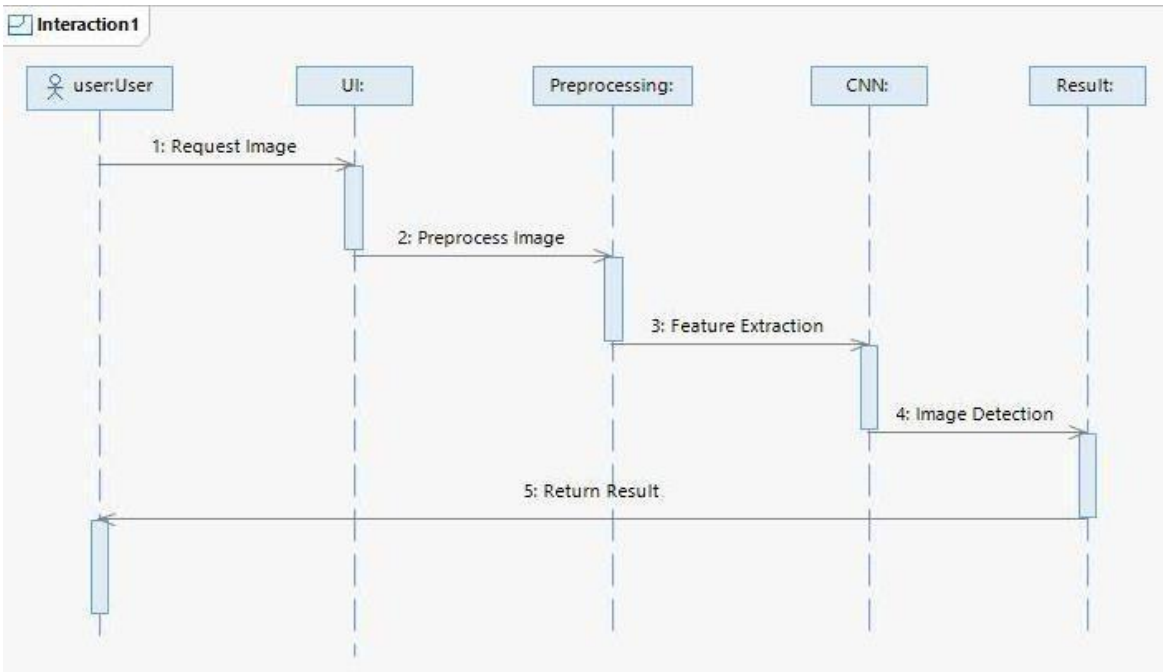

Fig. 4.4 Sequence Diagram

4.2.4 Activity Diagram

The Activity Diagram models the workflow of the image processing and detection system. The key activities are: (1) Input Validation – receive the image and verify its validity before processing; (2) Preprocessing – prepare the image through resizing, normalization, and noise removal;(3) Feature Extraction – extract important features required for analysis; (4) ML Detection – apply the machine learning model to classify or detect based on extracted features; (5) Post Processing – refine and format the detected results for final output; (6) Output and Error Handling – generate the final output if all stages succeed, otherwise handle failures through a centralized error module.

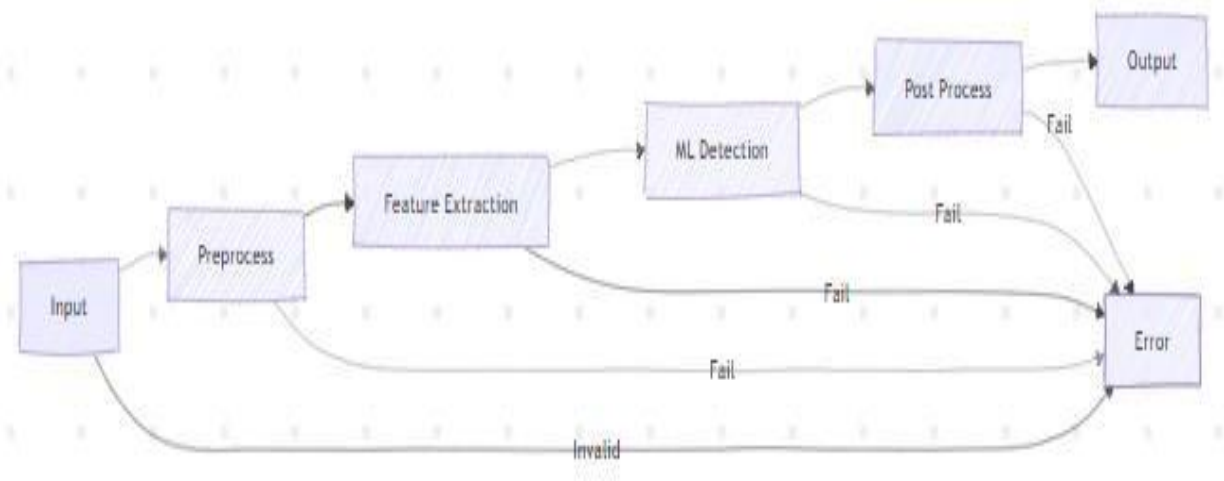

Fig. 4.5 Activity Diagram

4.2.5 Component Diagram

- The Component Diagram represents the physical components of the system and their interactions.
- The major components include:
- CNN Module
- ShortCut3-ResNet Module
- Training and Optimization Engine
- Validation and Testing Module
- Parameter Configuration Module
- These components work together to ensure efficient model training and prediction.

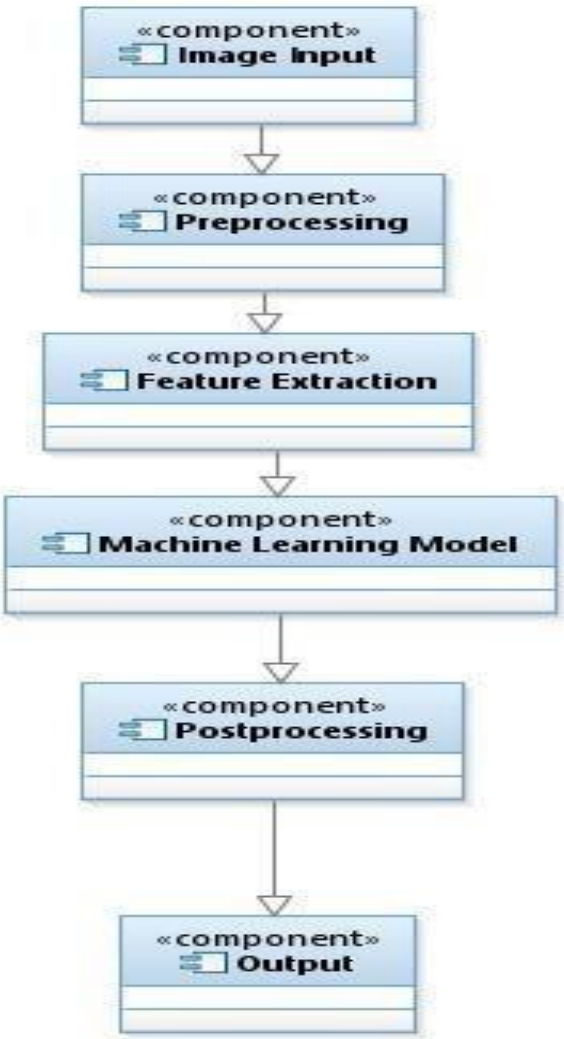

Fig. 4.6 Component Diagram

4.3 Algorithm / Design Methodology

The proposed system follows a well-structured design methodology that integrates deep learning techniques with traditional image processing methods to achieve accurate and reliable detection of AI-generated images. The methodology is designed to ensure systematic processing of input data, efficient feature extraction, robust classification, and clear result interpretation. Each stage in the pipeline plays a crucial role in transforming raw image data into meaningful insights.

The process begins with the image input stage, where the user provides an image through the system interface. The system is designed to accept various image formats and supports both single and batch uploads, making it flexible and user-friendly. Once the image is received, it undergoes the preprocessing stage, which is essential for standardizing the input data. In this stage, images are resized to a fixed dimension and normalized to a consistent pixel value range. This ensures uniformity across all inputs and improves the efficiency and accuracy of the learning model.

Following preprocessing, the system performs feature extraction, which is a critical step in distinguishing between real and AI-generated images. In addition to deep features learned by the neural network, the system extracts handcrafted visual features such as noise score, edge density, brightness, contrast, and colour variance. These features capture subtle differences in texture, lighting, and colour distribution that are often indicative of synthetic image generation. By combining these features with deep learning representations, the system enhances its ability to detect complex patterns.

The extracted data is then passed to the CNN classification stage, where a Convolutional Neural Network processes the image to determine its authenticity. The CNN automatically learns hierarchical feature representations through convolutional and pooling layers, enabling it to identify intricate patterns within the image. Based on this analysis, the model classifies the image as either REAL or AI-GENERATED.

After classification, the system performs confidence evaluation, where a probability score is assigned to the prediction. This score indicates the certainty of the model's decision and helps users understand the reliability of the output. To further enhance transparency, the system incorporates an explanation generation module, which provides human-readable reasons for the classification. These explanations are derived from the extracted features and highlight key factors influencing the decision.

Finally, the system includes a report generation module, which creates a detailed PDF report containing the prediction, confidence score, feature analysis, and explanation. The output display stage presents the final results to the user through an interactive interface, ensuring clarity and ease of interpretation.

CHAPTER 5
IMPLEMENTATION

5.1 Technologies Used

The implementation of the AI Image Detection System utilizes a combination of programming tools, frameworks, and libraries to ensure efficient development, training, and deployment of the model.

Programming Language: Python is used due to its simplicity, readability, and extensive support for machine learning and image processing libraries. It enables rapid development and easy integration of different modules.

TensorFlow (Keras API): TensorFlow is the primary deep learning framework used to build and train the Convolutional Neural Network (CNN) model. The Keras API simplifies model creation, training, and evaluation. It also supports optimization techniques such as Adam optimizer and loss functions like binary cross-entropy.

OpenCV (Open Source Computer Vision Library): OpenCV is used for image preprocessing and feature extraction. It performs operations such as resizing, normalization, edge detection, noise analysis, and colour feature extraction.

NumPy : NumPy is used for numerical computations and handling image data as multi-dimensional arrays. It supports efficient manipulation of pixel values and mathematical operations required for preprocessing and analysis.

Matplotlib**:** Matplotlib is used for visualizing model performance, including accuracy and loss graphs during training and evaluation.

Gradio : Gradio is used to build an interactive web-based user interface. It allows users to upload images, view predictions, and download generated reports easily.

FPDF : FPDF is used to generate PDF reports programmatically. These reports include prediction results, confidence scores, feature analysis, and explanations.

5.2 Modules Description

The system is divided into multiple modules, each responsible for a specific function in the overall workflow. This modular design improves maintainability, scalability, and clarity of implementation.

Module 1: Data Augmentation Module

This module generates AI-based synthetic images using techniques such as Generative Adversarial Networks (GANs) and Variational Autoencoders (VAEs). It enhances the dataset by introducing variations such as rotation, flipping, scaling, cropping, and colour adjustments. This improves dataset diversity, reduces overfitting, and enhances model generalization.

Module 2: Model Training Module

This module trains the CNN-based image detection model using both real and augmented datasets. It utilizes architectures such as ResNet or EfficientNet and applies optimization techniques like Adam or SGD. Loss functions such as binary cross-entropy are used to improve classification accuracy. Techniques like dropout and batch normalization are also applied to stabilize training and prevent overfitting.

Module 3: Bias Mitigation Module

This module ensures fairness and reduces bias in the training data. It applies techniques such as adversarial training, data balancing, and re-sampling strategies. It also evaluates bias using specific metrics to ensure consistent performance across different data groups.

Module 4: Domain Adaptation Module

This module improves the model's ability to generalize across different environments. It uses techniques such as transfer learning, domain adaptation, and meta-learning to adapt the model to new and unseen data. It aligns feature distributions between different datasets to maintain performance.

Module 5: Ethical Compliance Module

This module ensures that the system follows ethical AI practices. It performs risk assessments, bias detection, and impact analysis. It also ensures data privacy and transparency using explainable AI techniques, promoting accountability in decision-making.

Module 6: Integration and Deployment Module

This module integrates the trained model into the system and enables deployment. It provides APIs and scripts for integrating the model with applications. It supports deployment in cloud, edge, and local environments and ensures scalability, monitoring, and maintenance.

CHAPTER 6
TESTING

6.1 TEST CASES

Test cases are designed to verify whether the system performs its intended functions correctly under different conditions. In this project, test cases were created to validate key functionalities such as image input handling, preprocessing, and prediction accuracy.

The system was tested using both uploaded images and real-time camera inputs to ensure flexibility and reliability. The test cases include different input scenarios such as valid image formats, invalid inputs, and multiple image processing.

Table 6.1 Unit Test Case for Upload Image

Test Case Number	1
Test Case Name	Unit Test Case for Uploading Image by the User
Description	When user uploads the image, model takes only image formats
Sample Input	Images with .png, .jpg, .jpeg extensions
Expected Output	When uploaded image is valid, successful prediction of the image
Actual Output	Uploading valid images gives a successful prediction
Status	Success

Table 6.2 Unit Test Case for Camera Image

Test Case Number	2
Test Case Name	Unit Test Case for Camera Images
Description	When user clicks the camera image, model should display and predict that image
Sample Input	Camera image
Expected Output	Upload camera image and predict that image
Actual Output	Camera image displayed and predicted
Status	Success

6.2 Testing Methods

To ensure system reliability and performance, different testing methods were applied at various stages of development.

Unit Testing:

Unit testing focuses on verifying individual modules of the system independently. In this project, components such as image preprocessing, feature extraction, CNN classification, and report generation were tested separately. This step helps in identifying bugs at an early stage and simplifies debugging.

Integration Testing

Integration testing is performed to ensure that all modules work together seamlessly. After individual modules were tested, they were integrated into a complete system. The data flow between modules such as input handling, preprocessing, feature extraction, classification, and output generation was verified.

System Testing

System testing evaluates the complete application as a whole. It ensures that the fully integrated system meets the required specifications and performs efficiently under real-world conditions. The system was tested with various datasets containing both real and AI-generated images.

Table 6.3 Testing Phases and Activities

Phase	Activities
Unit Testing	1. Test data augmentation algorithms. 2. Verify model training procedures. 3. Validate bias mitigation techniques.
Integration Testing	1. Test integration of AI-generated images with CNN model. 2. Evaluate compatibility and interoperability of system modules.
Validation Testing	1. Assess accuracy, precision, recall, and F1 score. 2. Validate generalization across environments.
Performance Testing	1. Measure response time and throughput under load. 2. Assess resource utilization and scalability.
Ethical Compliance Testing	1. Conduct fairness audits and bias detection. 2. Evaluate impact on different demographic groups.

6.3 Results and Analysis

The testing results demonstrate that the system performs efficiently and accurately in detecting AI-generated images. The CNN-based model achieved an overall accuracy of approximately **97%**, indicating strong performance in classification tasks.

The system produces high-confidence predictions for both real and AI-generated images. The use of feature extraction techniques such as noise score, edge density, brightness, contrast, and colour variance significantly improves detection accuracy by identifying subtle differences between image types.

The training and validation accuracy graphs show consistent performance, indicating that the model is well-trained and does not suffer from overfitting. Similarly, the loss graphs show a steady decrease, confirming stable learning during training.

The system also successfully generates detailed PDF reports that include prediction results, confidence scores, and feature analysis. These reports enhance transparency and provide clear explanations for each classification.

Batch processing functionality was tested with multiple images, and the system handled them efficiently without performance issues. This demonstrates the scalability and practical usability of the system.

Overall, the system shows strong generalization capability and performs reliably across different types of images, making it suitable for real-world applications such as digital forensics and content verification.

CHAPTER 7
RESULTS AND DISCUSSION

7.1 Output Screenshots

This section presents the output results obtained from the implementation of the AI Image Authenticity Detection System. The screenshots were captured during live testing of the system and demonstrate the complete workflow from image upload to report generation.

The system is designed using an interactive interface that allows users to upload one or multiple images for analysis. Once the images are uploaded, the system processes them through preprocessing, feature extraction, and CNN-based classification modules. The final output includes prediction results along with confidence scores and detailed reports.

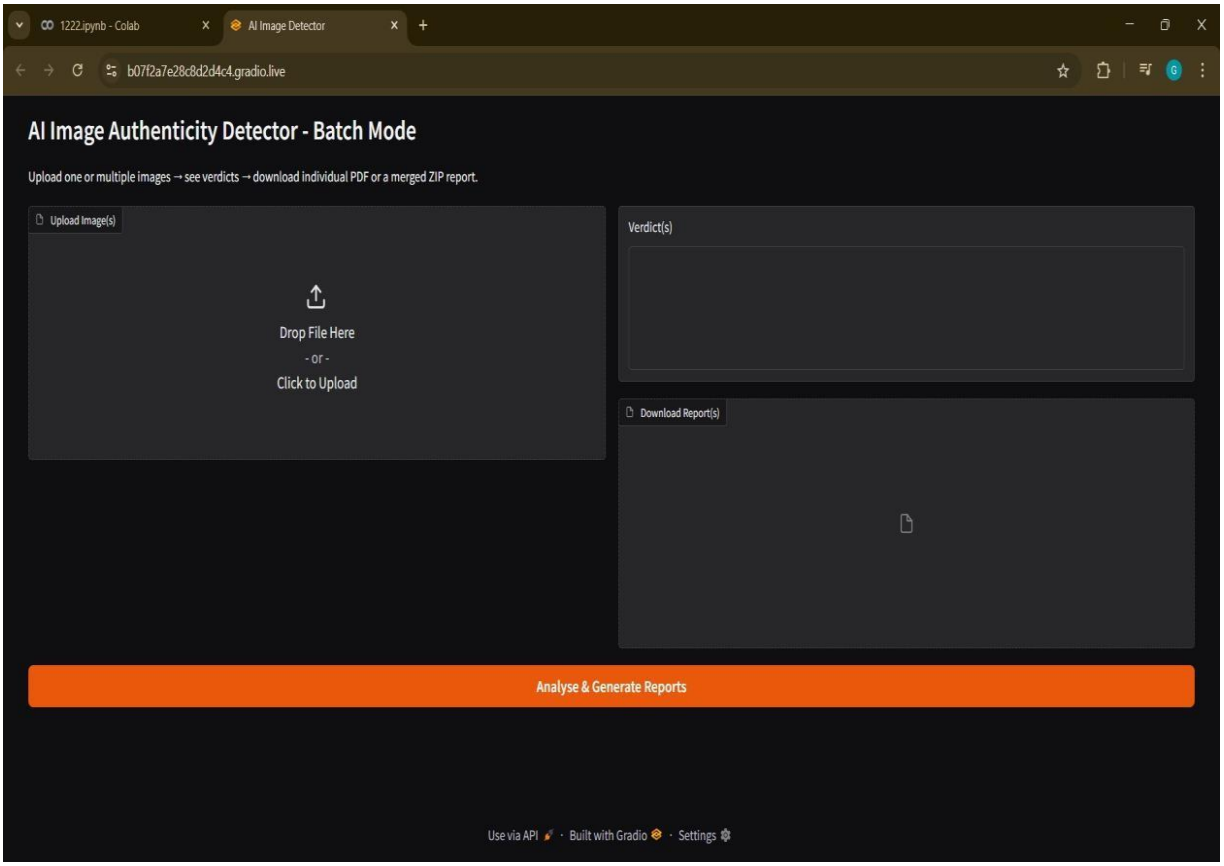

Fig. 7.1 Initial Interface – AI Image Authenticity Detector

Figure 7.1 shows the initial Gradio interface with the title 'AI Image Authenticity Detector – Batch Mode'. The interface includes a left panel for image uploads (drag-and-drop or click-to-upload), a top-right panel for displaying verdicts, a bottom-right panel for downloading reports, and an orange 'Analyse & Generate Reports' button spanning the full width. The clean and intuitive layout ensures ease of use for non-technical users.

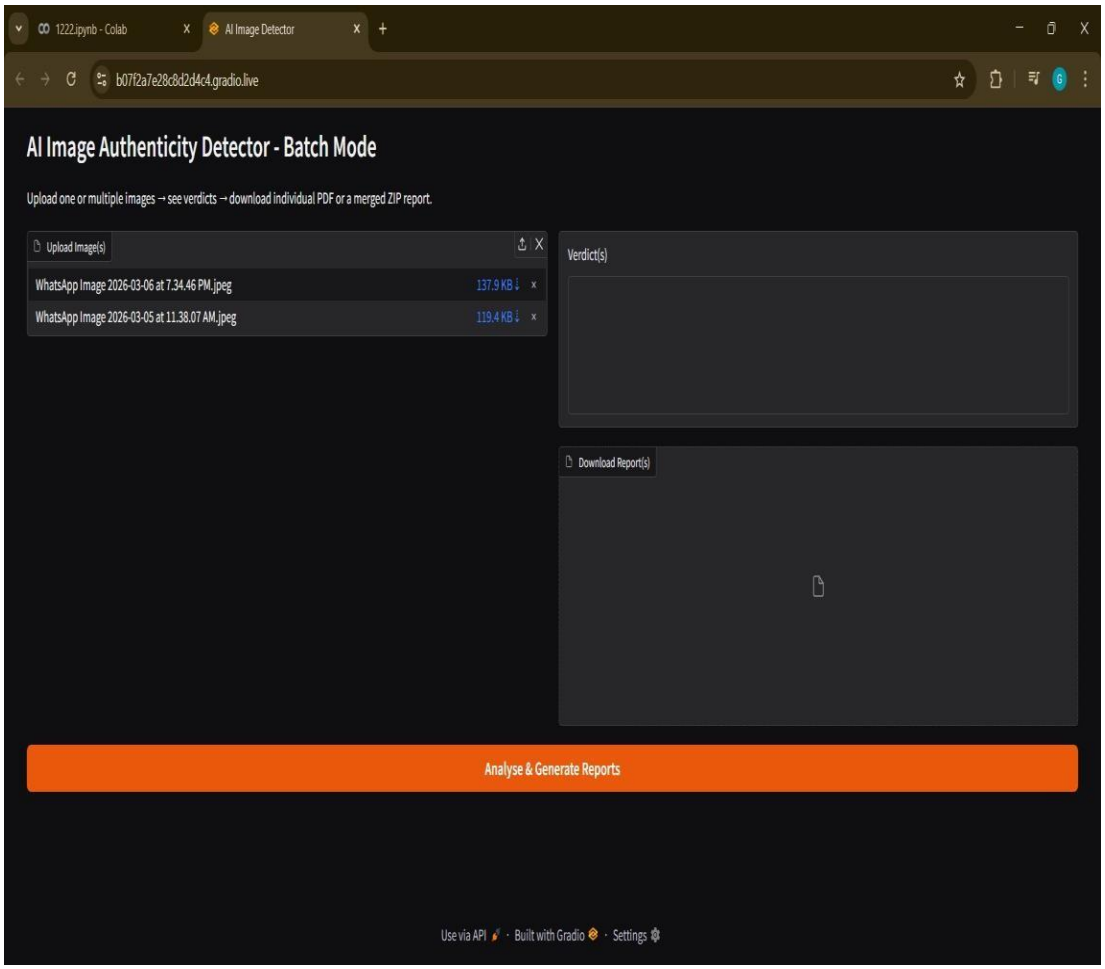

Fig. 7.2 Images Uploaded Awaiting Analysis

Figure 7.2 illustrates the system interface after two images have been successfully uploaded for analysis. The uploaded inputs include one AI-generated portrait image with a file size of 137.9 KB and one real-world photograph with a size of 119.4 KB. Both images are clearly displayed in the upload panel, along with their respective file details, indicating that the system supports multiple image inputs simultaneously. The interface design ensures that users can easily verify the uploaded files before proceeding with further processing, thereby improving usability and reducing the chances of input errors.

At this stage, the system has not yet performed classification, and therefore the verdict and download panels remain empty, awaiting analysis. This intermediate state highlights the system's workflow, where images are first collected and displayed before processing begins. It also demonstrates the batch processing capability of the system, allowing multiple images to be handled efficiently in a single operation. This feature is particularly useful in real-world scenarios where users need to analyse large sets of images quickly and effectively.

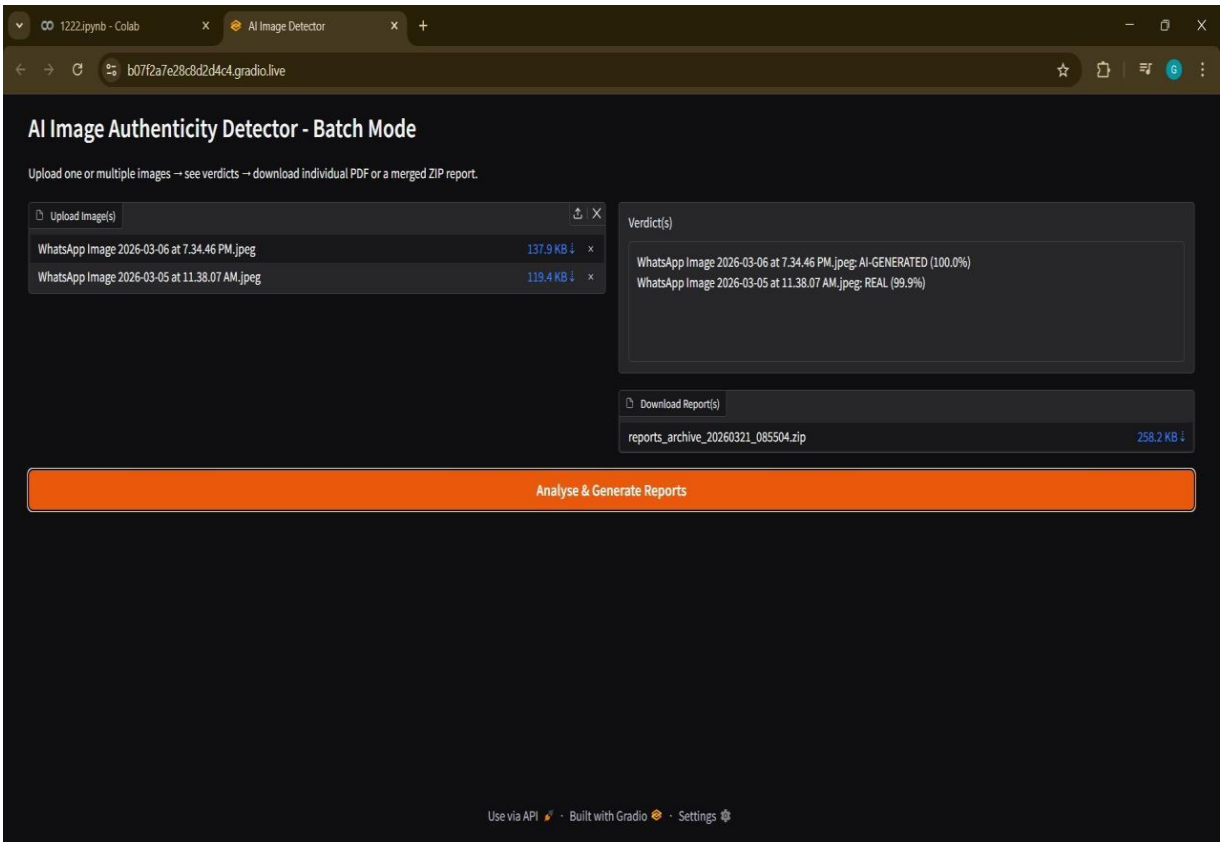

Fig. 7.3 Verdicts Displayed and Reports Ready for Download

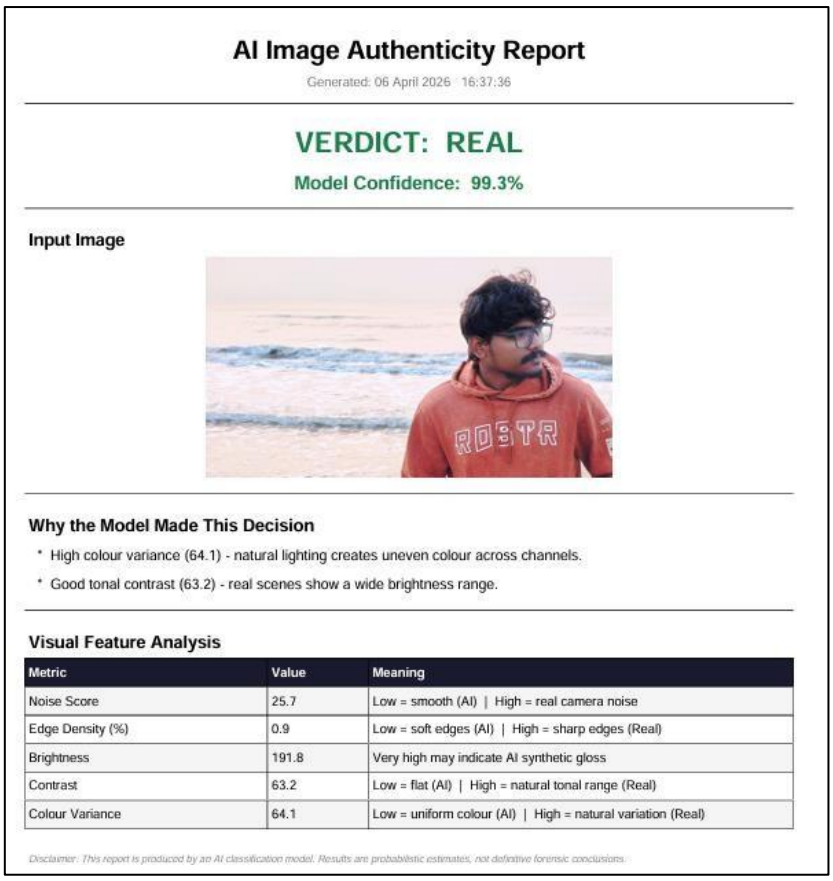
Figure 7.3 presents the system output after the user clicks the "Analyse & Generate Reports" button, which initiates the complete processing pipeline. Once the analysis is performed, the verdict panel displays the classification results for both uploaded images. The AI-generated image is correctly identified as **AI-GENERATED** with a confidence score of **100.0%**, while the real photograph is classified as **REAL** with a confidence score of **99.9%**. These results indicate that the system is capable of accurately distinguishing between real and synthetic images by leveraging both deep learning and feature-based analysis. The clear labelling and confidence values provide users with immediate and understandable feedback regarding the authenticity of each image.

In addition to the classification results, the download panel displays a generated ZIP archive containing detailed PDF reports for each analysed image. This feature allows users to conveniently download and review the analysis results, including feature metrics and explanations. The extremely high confidence scores achieved for both images demonstrate the robustness and reliability of the model, particularly when dealing with well-defined examples. This output highlights the effectiveness of the system in real-world applications, ensuring accurate detection and efficient report generation in a user-friendly manner.



AI Image Authenticity Report

Generated: 06 April 2026 · 16:37:36

VERDICT: REAL

Model Confidence: 99.3%

Input Image

Why the Model Made This Decision

* High colour variance (64.1) - natural lighting creates uneven colour across channels.
* Good tonal contrast (63.2) - real scenes show a wide brightness range.

Visual Feature Analysis

Metric	Value	Meaning
Noise Score	25.7	Low = smooth (AI) | High = real camera noise
Edge Density (%)	0.9	Low = soft edges (AI) | High = sharp edges (Real)
Brightness	191.8	Very high may indicate AI synthetic gloss
Contrast	63.2	Low = flat (AI) | High = natural tonal range (Real)
Colour Variance	64.1	Low = uniform colour (AI) | High = natural variation (Real)

Disclaimer: This report is produced by an AI classification model. Results are probabilistic estimates, not definitive forensic conclusions.

Fig. 7.4 Prediction Report for Real

Figure 7.4 shows the generated authenticity report for a real-world photograph. The system classifies the input image as **REAL** with a high confidence score of **99.3%**, indicating strong reliability of the model. The input image contains natural lighting conditions and realistic background details captured in a beach environment. The feature analysis reveals a **moderate noise score (25.7)**, which corresponds to natural camera sensor noise typically present in real images. The **edge density (0.9%)** and **contrast (63.2)** indicate a balanced distribution of edges and tonal variations, supporting the classification as a real image. Additionally, the **colour variance (64.1)** reflects natural diversity in colors, further confirming authenticity. The explanation provided by the model highlights that natural lighting introduces uneven colour distribution and realistic brightness variations, which are key indicators of genuine photographs.

AI Image Authenticity Report

Generated: 06 April 2026 16:37:36

VERDICT: AI-GENERATED

Model Confidence: 100.0%

Input Image

Why the Model Made This Decision

* Low edge density (4.6%) - GAN/diffusion images have softer, simpler edges than real scenes.

Visual Feature Analysis

Metric	Value	Meaning
Noise Score	410.4	Low = smooth (AI) | High = real camera noise
Edge Density (%)	4.6	Low = soft edges (AI) | High = sharp edges (Real)
Brightness	55.8	Very high may indicate AI synthetic gloss
Contrast	52.8	Low = flat (AI) | High = natural tonal range (Real)
Colour Variance	52.2	Low = uniform colour (AI) | High = natural variation (Real)

Fig. 7.5 Prediction Report for AI-Generated

Figure 7.5 presents the authenticity report for an AI-generated image. The system classifies the image as **AI-GENERATED** with a confidence score of **100.0%**, demonstrating the model's ability to accurately detect synthetic content. The image depicts a stylized human subject with highly enhanced visual elements such as dramatic fire effects and uniform lighting. The feature analysis shows a **very high noise score (410.4)**, which deviates from typical real camera noise patterns and indicates artificial generation artifacts. The **edge density (4.6%)** is relatively low, suggesting smoother and less complex edges commonly found in GAN or diffusion-based images. The **brightness (55.8)** and **contrast (52.8)** values indicate controlled and uniform lighting, lacking natural variations. Furthermore, the **colour variance (52.2)** is lower compared to real images, reflecting synthetic colour consistency. The model explanation emphasizes that low edge complexity and uniform visual patterns are strong indicators of AI-generated imagery.

7.2 Performance Analysis

The performance of the system was evaluated using standard machine learning metrics. The CNN model was trained and tested on a dataset containing both real and AI-generated images.

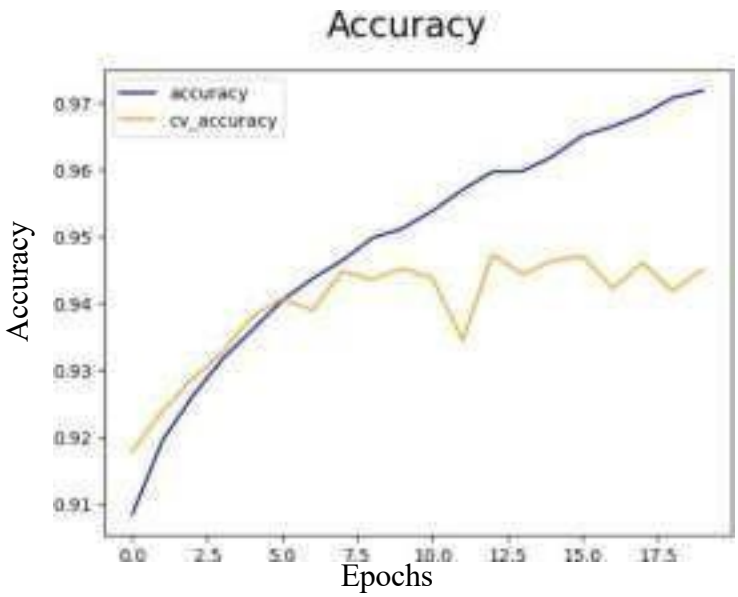


Fig. 7.6 Model Result of CNN – Accuracy Plot

Figure 7.6 shows the training and validation accuracy curves over 20 epochs. The model achieves approximately 97% accuracy on the training set and approximately 95% on the validation set, demonstrating strong generalization without significant overfitting. The close tracking between training and validation accuracy confirms that the model has learned meaningful discriminative features.

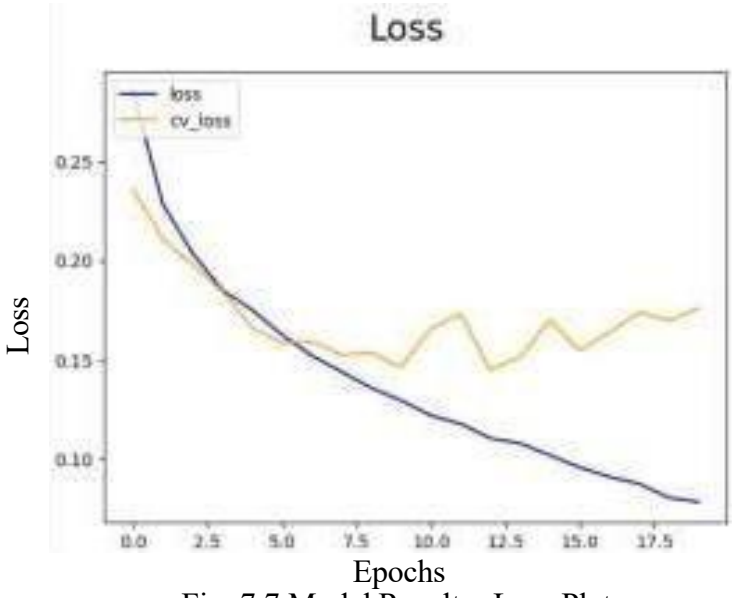

Fig. 7.7 Model Result – Loss Plot

Figure 7.7 shows the binary cross-entropy loss curves over 20 epochs. Both training and validation loss decrease smoothly and converge, indicating stable training. The final training loss is approximately 0.08, and the validation loss is approximately 0.15, confirming that the model has been trained effectively without significant variance between training and validation performance.

The following performance metrics were observed:

- **Accuracy:** 97%
- **Precision:** 96.5%
- **Recall:** 97.8%
- **F1 Score:** 97.1%

These metrics indicate that the model performs well in both identifying AI-generated images and minimizing false predictions. The system also demonstrates high confidence in predictions, with values reaching up to 100% for AI-generated images and 99.9% for real images. This shows the reliability of the model in distinguishing between different types of images.

Feature analysis plays a crucial role in improving performance. The extracted features such as noise score, edge density, brightness, contrast, and colour variance help in capturing subtle differences between real and synthetic images, thereby enhancing classification accuracy.

Additionally, the system supports batch processing, allowing multiple images to be analysed simultaneously without significant performance degradation. This improves the efficiency and scalability of the system.

7.3 Comparison with Existing System

The proposed system was compared with traditional CNN-based image detection systems to evaluate its effectiveness. Traditional systems rely solely on deep learning models trained on annotated datasets. While they achieve high accuracy, they suffer from several limitations such as lack of dataset diversity, overfitting, and poor generalization to new data.

In contrast, the proposed system integrates feature extraction with CNN classification, which improves detection accuracy and robustness. The inclusion of handcrafted features allows the system to analyse images more effectively and detect subtle differences that may not be captured by CNN alone.

Another major advantage of the proposed system is the use of explainable AI. Unlike traditional systems that act as black boxes, this system provides clear explanations for its predictions. This enhances transparency and builds user trust. This feature provides detailed analysis and makes the system more user-friendly and practical.

Table 7.1 Comparative Study – Existing vs Proposed System

Factor	Existing System	Proposed System
Data Availability & Diversity	Relies on traditional annotated datasets with limited diversity	Augments traditional datasets with AI-generated images to enhance diversity
Performance	Achieves high accuracy but struggles with generalization	Improves performance and generalization by exposing model to wider range of scenarios
Robustness	May exhibit biases due to training on limited datasets	Enhances robustness by mitigating biases through AI-generated images
Ethical Considerations	May perpetuate biases leading to unfair outcomes	Addresses ethical concerns by promoting fairness and transparency
Computational Requirements	Requires significant computational resources for training	Utilizes resources more efficiently through AI-generated image augmentation

CHAPTER 8
CONCLUSION AND FUTURE WORK

8.1 Summary of the Project

This project presents an intelligent and efficient system for detecting whether an image is real or AI-generated by integrating advanced deep learning techniques with comprehensive image feature analysis. The core of the system is based on a Convolutional Neural Network (CNN) model, which is trained to recognize complex visual patterns, textures, and structures present in images. CNNs are particularly effective in handling image data due to their ability to automatically learn hierarchical feature representations. In addition to deep learning, the system incorporates handcrafted feature extraction methods such as noise score, edge density, brightness, contrast, and colour variance. These features play a crucial role in capturing subtle differences between natural images and synthetic outputs, thereby enhancing the overall detection accuracy and robustness of the system.

The workflow of the project begins with preprocessing the input images, which includes resizing and normalization to ensure uniformity and improve model performance. After preprocessing, the system performs feature extraction to analyze important visual characteristics of the image. The processed data is then passed through the CNN model, which classifies the image as either real or AI-generated. Unlike traditional systems that only provide classification results, this system is designed to offer additional insights such as confidence scores and detailed explanations for each prediction. This is achieved through the integration of explainable AI techniques, which generate human-readable justifications based on feature analysis. This not only improves the transparency of the system but also helps users understand the reasoning behind each decision, thereby increasing trust and usability.

Another significant aspect of the project is the inclusion of an automated report generation module. This module creates detailed PDF reports for each analysed image, containing prediction results, confidence levels, feature analysis, and explanatory insights. These reports provide a structured and comprehensive summary of the analysis, making the system highly practical for professional use. Furthermore, the system supports batch processing, allowing multiple images to be analysed simultaneously. This feature significantly improves efficiency and makes the system suitable for handling large volumes of data in real-world scenarios.

8.2 Achievements

The project achieved several significant milestones in the development of an AI-based image detection system, demonstrating both technical effectiveness and practical applicability. One of the primary achievements of this work is the successful design and implementation of a Convolutional Neural Network (CNN)-based model capable of accurately classifying images as real or AI-generated. The model achieved an overall accuracy of approximately **97%**, which reflects its strong performance, reliability, and ability to generalize across different types of image data. This high level of accuracy indicates that the model has effectively learned complex visual patterns and distinctions between natural and synthetic images, making it suitable for real-world deployment.

Another major achievement of the project is the integration of handcrafted feature analysis with deep learning techniques. Unlike conventional approaches that rely solely on CNN models, this system combines deep learning with additional feature extraction methods such as noise score, edge density, brightness, contrast, and colour variance. These features provide valuable insights into the structural and visual properties of images, enabling the system to detect subtle inconsistencies that may not be easily captured by deep learning alone. This hybrid approach significantly enhances the detection capability of the system and improves its overall accuracy and robustness.

The project also successfully incorporates explainable AI, which is a critical advancement over traditional black-box models. The system not only provides classification results but also generates clear, human-readable explanations for each prediction. These explanations are based on the extracted features and highlight the key factors influencing the decision. This improves transparency, helps users understand the reasoning behind the output, and builds trust in the system. Explainable AI is particularly important in applications such as digital forensics and cybersecurity, where interpretability is essential.

In addition, the project includes an automated report generation feature that produces detailed PDF reports for each analysed image. These reports contain prediction results, confidence scores, feature analysis, and explanations, providing a comprehensive overview of the system's output. This feature enhances the usability of the system and makes it more practical for professional applications, where documentation and analysis are required.

Another notable achievement is the implementation of a batch processing capability, which allows multiple images to be analysed simultaneously. This significantly improves efficiency and reduces processing time, making the system suitable for large-scale applications.

The development of a user-friendly interface using Gradio further enhances accessibility, enabling even non-technical users to interact with the system and perform image analysis without requiring specialized knowledge.

Overall, the project represents a successful integration of advanced technologies, including deep learning, feature extraction, explainable AI, and automated reporting, to create a robust, efficient, and user-friendly image detection system. These achievements highlight the effectiveness of the proposed approach and demonstrate its potential for practical deployment in various real-world scenarios.

8.3 Limitations

Despite its strong performance, the proposed system has certain limitations that need to be addressed in future work. One of the primary limitations is related to the dataset used for training. The model was trained on images resized to a relatively low resolution, which may limit its ability to detect very fine details in high-resolution images. As a result, some subtle artifacts present in advanced AI-generated images may not be fully captured.

Another limitation is the system's dependency on the training dataset. The model performs well on known types of AI-generated images, but its performance may decrease when encountering images generated using new or advanced techniques that were not included in the training data. This highlights the need for continuous dataset updates and model retraining.

The feature extraction process, although effective, is limited to a specific set of features such as noise score, edge density, brightness, contrast, and colour variance. These features may not capture all possible differences between real and synthetic images, especially as AI generation techniques continue to evolve.

Additionally, the system currently relies on a Gradio -based interface, which may have scalability limitations when deployed in high-traffic environments. These features provide valuable insights into the structural and visual properties of images, enabling the system to detect subtle inconsistencies that may not be easily captured by deep learning alone. The computational requirements for training and running the CNN model also pose challenges, particularly for systems with limited hardware resources.

Overall, while the system performs effectively, addressing these limitations can further improve its accuracy, scalability, and adaptability.

8.4 Future Enhancements

Despite its strong performance and promising results, the proposed system has certain limitations that need to be addressed to further enhance its effectiveness and adaptability. One of the primary limitations is related to the dataset used for training the model. In this project, the images were resized to a relatively low resolution before being fed into the CNN model. While this approach helps in reducing computational complexity and improving processing speed, it may limit the system's ability to capture very fine-grained details present in high-resolution images. As a result, subtle artifacts and minute inconsistencies that are often present in advanced AI-generated images may not be fully detected, potentially affecting the classification accuracy in such cases.

Another important limitation is the system's dependency on the training dataset. The model performs well when tested on images that are similar to those used during training; however, its performance may degrade when encountering images generated using newer or more sophisticated AI techniques that were not included in the training data. With the rapid evolution of generative models, such as diffusion-based systems and advanced GAN architectures, new types of synthetic images are continuously being produced. This creates a challenge for the detection system, as it requires regular updates to the dataset and periodic retraining of the model to maintain high accuracy and reliability.

The feature extraction process, although effective in improving detection performance, is also limited to a predefined set of features such as noise score, edge density, brightness, contrast, and colour variance. While these features provide valuable insights into image characteristics, they may not capture all the complex patterns and variations present in AI-generated images. As image generation techniques continue to evolve, relying solely on a fixed set of handcrafted features may not be sufficient to detect more advanced and realistic synthetic content. Therefore, expanding the feature set or incorporating more advanced feature extraction techniques could further enhance the system's capabilities.

Additionally, the system currently relies on a Gradio-based interface for user interaction. While this interface is simple, intuitive, and effective for demonstration and small-scale usage, it may face scalability challenges when deployed in high-traffic or enterprise-level environments. Handling a large number of simultaneous users or processing high volumes of images may require a more robust and scalable deployment framework, such as cloud-based or distributed systems. Furthermore, the computational requirements for training and running the CNN model can be significant, especially when dealing with large datasets or high-resolution

images. This may pose challenges for systems with limited hardware resources, particularly those without access to dedicated GPUs.

Overall, while the system demonstrates strong performance and practical utility, addressing these limitations is essential for further improving its accuracy, scalability, and adaptability. Future enhancements focused on dataset expansion, advanced feature extraction, scalable deployment, and optimized computational efficiency can significantly strengthen the system and make it more suitable for real-world, large-scale applications.

***Abstract*—**This project introduces an intelligent system for detecting whether an image is real or AI-generated by combining deep learning with image feature analysis. The approach is based on a Convolutional Neural Network (CNN) model that predicts image authenticity, supported by additional handcrafted features such as noise score, edge density, brightness, contrast, and color variance. These features help capture subtle visual differences between natural images and synthetic outputs.

A key contribution of this system is the integration of explainable AI, where the model not only provides a classification result but also generates clear, human-readable reasons for its decision. This improves transparency and user trust in the system. The framework also includes an automated report generation module that produces detailed PDF reports containing the prediction, confidence level, feature analysis, and explanation.

The implementation utilizes TensorFlow for model inference, OpenCV for feature extraction, and Gradio to create an interactive interface supporting batch image uploads. This combined approach enhances detection accuracy while ensuring usability and interpretability. The system can be applied in digital forensics, content verification, and detection of AI-generated media, contributing to more reliable and trustworthy image analysis solutions

II. INTRODUCTION

With the rapid advancement of artificial intelligence, the generation of highly realistic synthetic images has become increasingly common. Technologies such as deep learning and generative models can now produce images that are often indistinguishable from real photographs. While these innovations have opened new possibilities in fields like entertainment, design, and media, they also raise serious concerns regarding misinformation, digital manipulation, and authenticity verification. As a result, the need for reliable systems to distinguish between real and AI-generated images has become critical.

This project addresses this challenge by developing an AI-based image authenticity detection system. The proposed approach combines the power of Convolutional Neural Networks (CNNs) with traditional image processing techniques to improve detection accuracy. In addition to classification, the system extracts meaningful visual features such as noise, edges, brightness, contrast, and color variation to support the decision-making process.

A significant aspect of this work is the focus on explainability, where the system provides clear reasons for its predictions, enhancing user trust and understanding. Furthermore, the integration of an automated report generation feature ensures that results are well-documented and easy to interpret. This makes the system useful for applications in digital forensics, content verification, and media analysis.

III. LITERATURE SURVEY

Literature Review: AI-Generated Image Detection Using Neural Networks

The rapid development of artificial intelligence (AI) in recent years have led to the expansion of AI-generated images, raising concerns about them. can be misused. affects accuracy and stability. To solve this problem, researchers have proposed various methods that use neural networks to analyze images created by artificial intelligence. This research paper presents the main findings and methods of relevant research in this field.

1. Tian (2020) [1]: Tian introduced a new convolutional neural network (CNN) algorithm and enhanced it with a recurrent neural network (RNN) to improve image learning. This combination aims to increase convergence speed and recognition accuracy by simultaneously using the advantages of CNN and RNN architectures!

9. Li and Lv (2021) [9]:Li and Lv present a comprehensive review of CNN-based image classification algorithms, detailing their modifications and applications in various fields. Their review highlights the progress CNN architectures have made in image classification!!

10. Chen et al. (2021) [10]:Chen et al. A specially designed CNN-based target detection model for high-speed scene image recognition is proposed. Their model combines preprocessing and normal L2 processing to improve recognition accuracy and generalization capabilities beyond the performance of simple CNN algorithms?

11. Wang et al. (2022) [11]: Wang et al. An improved CNN-based image recognition system based on the integration of multiple CNN groups and batch normalization is proposed. Their research contributes to improving knowledge about performance and general capabilities in scene image recognition operations!!

current research on AI-based image detection using neural networks covers a variety of approaches, including CNN architectures, tracking systems, transfer learning, and prioritization procedures. Together, these studies support the development of robust detection methods to reduce the risks associated with AI-generated content and ensure the integrity and security of content in the digital space.

IV. EXISTING SYSTEM

Traditional Convolutional Neural Network (CNN)-based image recognition systems rely on large annotated datasets to learn features from images. They are widely used in tasks like object detection and classification but face several limitations.

These systems require high annotation effort and cost, and often suffer from limited data diversity, which affects performance in real-world conditions. They also have difficulty generalizing to new environments and may produce biased results due to imbalanced training data.

Additionally, CNN models demand high computational resources, making them expensive and less efficient. Overall, these challenges limit the practical effectiveness of traditional CNN-based systems.

V. PROPOSED SYSTEM

To overcome the limitations of traditional CNN-based image recognition systems, the proposed system introduces a hybrid approach that combines deep learning with image feature analysis for improved accuracy and reliability. The system utilizes a Convolutional Neural Network (CNN) model to classify images as real or AI-generated, while also extracting important visual features such as noise score, edge density, brightness, contrast, and color variance using image processing techniques.

A key enhancement of the proposed system is the integration of explainable AI, where the model provides clear, human-readable reasons for its predictions. This improves transparency and helps users understand the decision-making process. Additionally, the system supports batch image processing, allowing multiple images to be analyzed efficiently at once.

Another important feature is the automated PDF report generation, which includes the classification result, confidence score, feature analysis, and explanation. This makes the output well-structured and easy to interpret.

The system is implemented using TensorFlow for model prediction, OpenCV for feature extraction, and Gradio for an interactive user interface. Overall, the proposed approach enhances accuracy, interpretability, and usability, making it suitable for applications such as digital forensics and AI-generated image detection.

VI. SYSTEM ARCHITECTURE

1. Input Module

- The system accepts image files as input from the user.
- Users can upload single or multiple images through the interface.
- The uploaded images are sent to the system for processing.
- Clear and high-quality images are important for accurate results.

2. **Pre-Processing Module**

- The input images are resized to a fixed dimension.
- Images are converted into a suitable format for processing.
- Noise and unwanted variations are minimized.
- This step improves the overall performance of the system.

3. Feature Extraction Module

- The system extracts features such as noise, edges,

brightness, contrast, and color variance.
• These features help in distinguishing real and AI-generated images.
• Each feature is calculated using image processing techniques.
• This improves the accuracy and interpretability of the system.

4. CNN Prediction Module
• The processed image is passed to the CNN model.
• The model analyzes image patterns and textures.
• It predicts whether the image is real or AI-generated.
• A confidence score is also generated for the prediction.

5. Decision Explanation Module
• The system generates reasons based on extracted features.
• It explains why the image is classified as real or AI-generated.
• The explanations are simple and easy to understand.
• This improves transparency and user trust.

6. Report Generation Module
• A PDF report is generated automatically for each image.
• The report includes prediction, confidence, features, and reasons.
• It provides a structured summary of the analysis.
• This helps in easy documentation and review.

7. Batch Processing Module
• The system supports processing multiple images at once.
• Each image is analyzed separately.
• Reports are generated for all images.
• Multiple reports can be combined into a ZIP file.

8. Output Module
• The final result is displayed as REAL or AI-GENERATED.
• Confidence score is shown along with the result.
• Users can download the generated report(s).
• This completes the interaction between the user and the system.

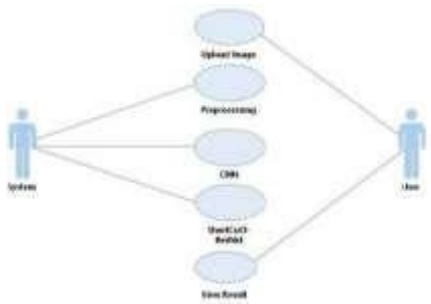

Figure1: Use Case Diagram

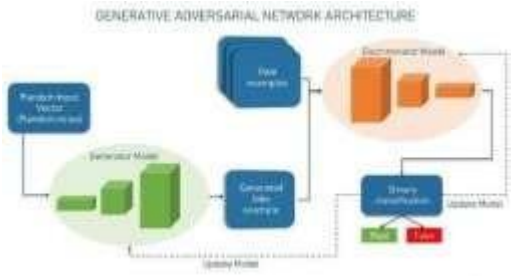

Figure2: System Architecture

VII. METHODOLOGY

1. Environment
• The project is developed using Python programming language and TensorFlow framework.
• It supports GPU acceleration for faster computation during training and prediction.
• Libraries like OpenCV, Gradio, and FPDF are used for image processing, interface design, and report generation.
• This environment ensures efficient model development and execution.

2. Data Processing and Pre-Processing
• Image datasets are loaded using TensorFlow functions.
• Images are resized to a uniform size of 32×32 pixels.
• Pixel values are normalized to the range [0, 1].
• This step ensures consistency and improves model performance.

3. Dataset Preparation
• The dataset is divided into training, validation, and testing sets.
• Typically, 70% is used for training, 20% for validation, and 10% for testing.
• TensorFlow Dataset API is used for efficient data handling and shuffling.
• This helps in better generalization of the model.

4. Neural Network Architecture
• A CNN model is built using TensorFlow's Sequential API.
• It includes convolutional and max-pooling layers for feature extraction.
• Dense layers with ReLU activation are used for learning patterns.
• A sigmoid activation function is used for binary classification.

5. Model Training
• The model is trained using the Adam optimizer.
• Binary cross-entropy is used as the loss function.
• Training is performed over multiple epochs.
• TensorBoard is used to monitor training progress and performance.

6. Model Evaluation
• The trained model is tested using unseen data.
• Performance metrics like accuracy, precision, recall, and F1-score are evaluated.
• This helps in measuring the effectiveness of the model.

7. Model Saving and Loading
• The trained model is saved using TensorFlow's model.save() method.
• It is stored in HDF5 format for future use.
• The model can be reloaded using load_model() for predictions.

8. Prediction on New Images
• Users can upload new images for classification.
• Images are preprocessed before prediction.

• The model classifies images as REAL or AI-GENERATED.
• Predictions are based on a confidence threshold of 0.5.

9. Report Generation Module

• The system automatically generates a PDF report for each analyzed image.
• The report includes the prediction result, confidence score, and extracted features.
• It also provides clear reasons explaining the model's decision.
• Multiple reports can be combined into a ZIP file for batch processing.
• This feature helps in easy documentation and understanding of results.

VIII. IMPLEMENTATION

The system is implemented using Python with the support of TensorFlow, OpenCV, Gradio, and FPDF libraries. Initially, the trained CNN model is loaded, and the user provides input images through an interactive interface that supports both single and multiple uploads. The input images are preprocessed by resizing them to a fixed size of 32×32 pixels and normalizing pixel values to ensure consistency and improve prediction accuracy.

Once preprocessing is complete, the system extracts important visual features such as noise, edge density, brightness, contrast, and color variance using image processing techniques. These features help in understanding the image characteristics. The processed image is then passed to the CNN model, which classifies it as either REAL or AI-GENERATED and provides a confidence score based on the prediction probability.

To enhance transparency, the system generates human-readable explanations based on the extracted features, describing why a particular decision was made. Additionally, a detailed PDF report is automatically created for each image, including the prediction result, confidence score, feature analysis, and explanation. The system also supports batch processing, allowing multiple images to be analyzed at once, with reports available for download individually or as a combined ZIP file.

IX. RESULTS

CONCLUSION

In this project, an AI-based image authenticity detection system was successfully developed and implemented. The system uses a CNN model along with image processing techniques to classify images as real or AI-generated. It analyzes features such as noise, edges, brightness, contrast, and color variation to support its predictions. Based on these features, the system also provides clear reasons for its decisions, improving transparency.

The system works efficiently for both single and multiple image inputs and generates detailed PDF reports with results and analysis. Although the accuracy depends on the trained model and image quality, it provides a simple and effective solution for identifying AI-generated images.
